**ABSTRACT**

An emergency moving device of an elevator includes a reduction gear ~~fixed on top of the car~~, several first gears coupled to a shaft of the reduction gear, a first connector releasably coupled to the car, a second connector affixed to the car and releasably coupled to the first connector, a fall-prevention device releasably coupling the first connector to the second connector, and chains respectively connected to the first connector and engaging the first gears. The ~~[[; the]]~~ first connector is coupled to the steel ropes ~~of the elevator~~ used for vertically displacing the elevator car. When ~~member; when~~ the car is stopped between floors by a power failure, the passengers press an emergency button to ~~make the fall-prevention device~~ uncouple the first connector from the second connector, so that the car is allowed to move downwardly relative to the first connector until it arrives at a next floor, with the reduction gear reducing speed of the car.
